

Thanks Flavie, to make the transition to the article.

*merge*  
... So, the article "Humanoid Path Planning for Rough Terrain Navigation" presents a trajectory planning approach for humanoid robots to navigate in ~~different~~ <sup>risky</sup> environments. This approach ~~combines~~ <sup>uses</sup> a path planner ~~with~~ <sup>a</sup> a balance controller and step planner to allow a robot like Atlas to move through challenging terrain in a fluid and natural way.

... The path planner uses the A\* algorithm (based on Dijkstra algorithm) to find an optimal trajectory through difficult ~~terrain~~ <sup>areas</sup> while minimizing effort costs and maximizing stability. To do this, the planner uses a height map ~~that represents the terrain~~ <sup>the cost</sup> and calculates ~~costs~~ <sup>costs</sup> to avoid hard-to-cross areas, as well as ~~effort costs~~ <sup>effort costs</sup> to minimize the amount of energy required for movement. ~~These costs are weighted to prioritize the stability and safety of the robot.~~ <sup>Of course, the</sup>

... The IHMC balance controller and step planner are then used to track the path calculated by the path planner. The step planner uses a map of flat regions to determine the best fulcrum points for each step of the robot. This map is generated from a high-resolution <sup>LIDAR</sup> point cloud ~~captured by the robot~~ <sup>and</sup> ~~the step planner~~ <sup>uses the A\* algorithm</sup> to find the best step sequence to follow the path ~~planner path~~ <sup>of the path planner</sup> ~~and~~ <sup>on the right, the generated trajectories in specific cases.</sup>

... As you can see on the board, we have different article pictures. On the left, ~~we have the point cloud~~ <sup>we have</sup> point cloud, which will be ~~used to generate the ground and the different volumes of the environment.~~ <sup>we have volumes and the ground generated by the LIDAR sensor</sup> ~~And on the right, the different trajectories generated by the algorithm in specific cases.~~

So, we can note that the robot will not try to jump over the stairs (as in example A and C) or to step over an obstacle (as in example B), because it would be too expensive in energy. Instead, he uses the environment has its advantage, as shown in example D.

*Of course, the algorithm*  
... ~~The proposed approach~~ <sup>was a major step</sup> was tested on the Atlas robot using ~~a variety of~~ <sup>risky</sup> challenging terrains. The results show ~~that the proposed path planning allows the robot to move through~~ <sup>that the proposed path planning allows the robot to move through</sup> a fluid and natural way. However, it should be noted that the A\* algorithm can sometimes encounter "dead end" problems, ~~where the planner spends a lot of time looking for a trajectory to reach the goal, which is not possible.~~ <sup>where the planner spends a lot of time looking for a trajectory to reach the goal, which is not possible.</sup> The authors suggest using a series of simplified metrics to improve ~~the efficiency of~~ <sup>the efficiency of</sup> the A\* algorithm and speed up trajectory planning.

... To conclude, the article trajectory planning approach ~~represents a significant advance~~ <sup>was a major step</sup> in the field of challenging terrain robotic navigation. The results obtained ~~on the Atlas robot demonstrate the~~ <sup>Results demonstrate</sup> approach feasibility and suggest research avenues to improve trajectory planning in risky terrain ~~on the Atlas robot~~ <sup>on the Atlas robot</sup>

*Finish this presentation*  
... To ~~present the results~~ <sup>present the results</sup> and show ~~the proposed results~~ <sup>the proposed results</sup>, I will let you watch ~~this short 2min video,~~ <sup>this short 2min video,</sup> which quickly presents the Atlas features pushed by this navigation algorithm.
